

Fedora 31 announcement, news and known issues

Once a year, we upgrade all the desktop systems to the latest version of Fedora, our Linux desktop operating system.

General information

- [Fedora 31 release notes](#)
- [Common Bugs and Known Issues](#)

Local links:

- [Linux desktop environments](#)
- [Fedora compatibility settings](#)
- [Fedora tips](#)

New in F31, or in our Fedora setup:

- Gnome 3.34 (see below for details)
 - Various Gnome shell extensions that you can load for yourself from <https://extensions.gnome.org/>
- Cloud integration: you can link your [Google Drive](#), [OwnCloud](#)/SurfDrive and some other cloud storage services the file manager (in addition to [Dropbox](#), which has been there for a couple of years).
Various online calendars can be integrated in the desktop calendar utility.
- **Python is now by default 3.7.** You can still call python2 to get a python 2.7 interpreter, but not all packages are being supported any more, and python 2.7 itself will be unsupported soon.
 - All python programs in the desktop and system utilities, are now using python 3.
 - Command python will now invoke python3 so **check your own scripts**.
- Wayland: the official Fedora release notes have a lot of information about Wayland, a replacement for the X11 graphics system. We don't use Wayland at this time, since it doesn't yet support many features that are needed in our type of work (remote graphics, VNC, various scientific programs, ...). So you can ignore all that is written about Wayland in the documentation.

- Applications using the “pango” text rendering engine (including Gnome, Cinnamon and MATE desktops) will no longer support bitmap fonts. If an application looks strange, you may have to select a different font for it (seen on terminal emulators, emacs with non-standard settings, possibly other applications)
- Mono (.NET compatible framework) has been updated to version 5. This may require rebuilding Mono apps.
- Beachbit (file cleaner) works, but seems to display wrong icons: the “search” icon is grayed out, but is available for clicking, and the “clean” icon to start cleaning, shows a s a grayed out x, so might be mistaken for an abort icon. The help text shown when the mouse is over the icon, shows the right description for the task.
- Removed software:
 - various python2 packages, where the latest version of the package no longer supports python2. Most notably:
 - astropy
 - python2-ipykernel
 - python2-pandas
 - python2-statsmodels
 - python2-scikit-*
 - python2-mpi4py
 - python2-sympy
 - python2-numexpr
 - If you still need these packages, a private install or virtualenv will still be possible, but you may have to explicitly install an older version (e.g. `pip2 install -user astropy==2.0.12`)
 - python2-matplotlib no longer has the QT backends (incompatible with current QT)
 - banshee (not yet ported to Mono 5.x)
 - MongoDB (no longer free software; this package wasn't present by default but could be installed on request, but no more)
 - Revelation password manager (known bug, see https://bugzilla.redhat.com/show_bug.cgi?id=1765902)
 - PhotoPrint (last release was 8 years ago, no longer compatible with current libraries)
 - Several obsolete or unlicensed gstreamer media plugins have been removed
 - Several compatibility libraries were dropped. These were libraries to run programs built with very old versions of the GNU compilers (gcc 3.3, 3.4 and 4.1). If you still have binaries from > 10 years ago, recompiling might be advisable.
- Renamed/replaced software
 - xmgrace is back after being called gracegtk in the previous versions
 - xine-ui is new name/version of the gxine media player
 - Python module asciitable is now part of astropy, at `astropy.io.ascii` (see <http://cxc.harvard.edu/contrib/asciitable/>)
Similarly, `pyfits` is now `astro.io.fits`
- The Flash plugin is still part of Google Chrome, but no longer provided as a firefox plugin. Google plans on dropping support soon, so don't count on it any longer.
- Java is now available in 3 versions: The last freely obtainable Oracle Java 8.x release; OpenJDK 8 and OpenJDK 11.

Known issues in Fedora 31

- The Gnome desktop will not run on computers without hardware accelerated graphics. If you want Gnome on these machines, choose “Gnome X11” or “Gnome fallback” from the menu on the login screen.

- VNC issues: Desktop environments that require hardware acceleration (3D desktop effects) are too heavy to be used inside a virtual desktop (VNC, X2GO). See [VNC desktop issues](#) for details and workarounds.
- TeX package `psfig`, which has been obsolete for a long time, has now almost completely stopped working. Converting documents to newer packages such as `graphics` or `graphicx` is recommended, and is usually easy.
- [ICAlient](#) (Citrix receiver, in use to reach the university “self service” pages) is only available as browser plugin, no longer as stand-alone application.
- CHECK Python package [tensorflow](#) explicitly doesn't support python 3.7. It can still be used in python 2.7, and if necessary, we can help you to set up a private virtualenv with python 3.6 and the required packages.
- CHECK: Gnome doesn't display *notification area* aka *system tray* icons any more by default. The fix is, to enable the `topicons` plus extension: open `gnome-tweaks`, and go to extensions to do that. After that, the icons such as status icons of dropbox, skype etc, will be in your top panel.

Some general observations and tips

- Gnome 3. Gnome 3 is a completely different desktop design, which makes the desktop look and behave a bit like a Tablet PC. Some people may like it, but if you don't, “Mate” is available as an alternative, to give you the experience of good old Gnome 2, or “Cinnamon”, for a more desktop-like version of the new Gnome, or try “Gnome Classic”.
[More on Gnome 3](#)
- Gnome applications: in every new release, more Gnome applications are rewritten in the style of the Gnome 3 desktop. This means: a separate application menu, displayed Mac-style in the top bar on the Gnome desktop, or under the application icon in other desktops, the most important actions displayed as buttons, and everything else in a menu at the top right in the application window.
See [desktop applications](#) for a table listing alternatives, in case you cannot get used to the new look.
- Cinnamon desktop tweaks: While Cinnamon is based on (and compatible with) Gnome 3, there are separate tools for its customization, eg, if you want to modify the programs that start in each session, use `cinnamon-session-properties` for that (also available from the settings overview).
[More on Cinnamon](#) or see the list of available [desktop applications](#)
- Programs that start with each session: A lot of programs are started by default in each desktop session. many of them are unnecessary; some of them are annoying or can cause problems. users can disable everything they don't need.
[More on session tweaking](#)
- The command `pmount` can be used to mount removable media (cdrom,dvd,usb-disks) from the commandline. E.g.: `pmount /dev/cdrom` mounts the cd/dvd as `/media/cdrom`.
- Emacs. Stating with Emacs version 24, the program contains quite a number of changes. For the most part: it tries to work nicer with current desktop systems, since the way people expect an X application to behave, have changed a lot over the years. Best to enable the KDE or Gnome clipboard manager, and enjoy the new feature of emacs and of your desktop the way they were programmed to be.
But emacs being emacs, all of this behaviour can be configured and fine-tuned. Read the news, available from the help menu (C-h n).
If you really, really, really want the old selection, cut and paste behaviour back, add this in your `.emacs`:

```
(setq select-active-regions nil)
(setq mouse-drag-copy-region t)
(setq x-select-enable-primary t)
(setq x-select-enable-clipboard nil)
(global-set-key [mouse-2] 'mouse-yank-at-click)
```

- Intel compilers: The Intel compilers (ifort,icc) are not enabled by default. The latest freely available version is 10.1, which can be loaded using `module load intel`. However, for most code, the GNU compilers are better than these old Intel compiler versions. (if you read that the Intel compiler has speed benefits, this probably refers to the very expensive current version, which we cannot install on a system-wide basis, or you are reading an obsolete webpage; the GNU compilers have gained significant speed of the last couple of years). If you really need the current Intel compilers, find funding, and be prepared to have a license locked to a single computer. Intel also provides personal free student licenses. As personal license, we cannot install it for you, unfortunately.
